

Chapter 19 Practice Problems

Jason Medcoff

1 Preliminaries

We know that changing magnetic fields induce currents, and that currents cause magnetic fields. With these principles, we can solve unknowns in situations with moving objects in magnetic fields.

2 Problems

2.1 Problem 1

The strength of the earth's magnetic field at the south magnetic pole is about 7×10^{-5} T. If we wanted to, we could rotate a coil in the field to generate alternating current electricity at 60 Hz. How many turns with a coil of area 0.016 square meters are needed to generate 120 V rms?

2.2 Problem 2

A .25 m long coil consists of 560 square turns with side length 6.5 cm. The coil is in a magnetic field of 1.2 T. The coil initially has its axis coinciding with the field direction, then it is turned 90 degrees about an axis perpendicular to the field direction in .2 ms. What is the induced emf?
